Abstract. Euclidean and non-Euclidean geometries can be considered as spaces that are invariant under a given group of transformations [8]. The geometry established by this approach is called Cayley-Klein geometry. Galilean 4-space is simply defined as a Cayley-Klein geometry of the product space $\mathbb{R} \times \mathbb{E}^3$ whose symmetry group is Galilean transformation group which has an important place in classical and modern physics.

Key words and Phrases: Galilean 4D space, Spherical indicatrices, ccr−curve, Involute-evolute curves, Bertrand curve, Helix, Spherical curve.

1. INTRODUCTION

Euclidean and non-Euclidean geometries can be considered as spaces that are invariant under a given group of transformations [8]. The geometry established by this approach is called Cayley-Klein geometry. Galilean 4-space is simply defined

as a Cayley-Klein geometry of the product space $\mathbb{R} \times \mathbb{E}^3$ whose symmetry group is Galilean transformation group which has an important place in classical and modern physics.

Discovering Galilean space-time is probably one of the major achievements of non relativistic physics. One may consider Galilean space as the limit case of a pseudo-Euclidean space in which the isotropic cone degenerates to a plane. This limit transition corresponds to the limit transition from the special theory of relativity to classical mechanics. Nowadays Galilean space is becoming increasingly popular as evidenced from the connection of the fundamental concepts such as velocity, momentum, kinetic energy, etc. and principles as indicated in [17].

A curve in 3D Galilean space is a graph of a plane motion. Note that such a curve is called a world line in 3-dimensional Galilean space. It is well known that the idea of world lines originates in physics and was pioneered by Einstein. The term is now often used in relativity theories, that is, general relativity and special relativity [18].

There is a vast of literature about researches on differential geometry of curves in both 3D and 4D Galilean space as explained below: firstly, Some special curves such as helices, involute-evolute curves were studied in [2, 5, 13, 14, 16]. Spherical curves and spherical indicatrix curves were examined in different spaces such as Galilean space, Heisenberg group, and de Sitter-space [1, 7, 9, 10, 11, 19].

Yılmaz constructed Frenet-Serret frame of a curve in 4D Galilean space and gave some characterizations of spherical curves in the same space [20]. Bektaş et al. characterized Mannheim curves in 4D Galilean space [4]. Yoon gave some characterizations of inclined curves by using their curvatures in 4D Galilean space [21]. Aydin et al. established equiform differential geometry of curves in 4D Galilean space [3]. Yoon et al. gave some characterizations of osculating curves by using their curvatures in 4D Galilean space [22]. Öztekin introduced special Bertrand curves and characterized them in 4D Galilean space [15].

In this paper, firstly we obtain the tangent, principal normal, binormal, and trinormal spherical indicatries of a regular curve in 4D Galilean space. Then we get their Frenet elements of these four special curves in terms of the Frenet elements of the original curve at the same space. Moreover, using these, we give some theorems characterizing these special curves as ccr-curves, general helix, involute-evolute curve pairs, and Bertrand mates.

2. Preliminaries

The 3-dimensional Galilean space $\mathbb{G}_3$ is the Cayley-Klein space equipped with the projective metric of signature $(0, 0, +, +)$. The absolute figure of the Galilean space consists of an ordered triple $\{w, f, I\}$, where $w$ is the ideal (absolute) plane, $f$ is the line (absolute line) in $w$ and $I$ is the fixed elliptic involution of points of $f$. 
where \( \cos^2 \delta_1 + \cos^2 \delta_2 + \cos^2 \delta_3 = 1 \) [20]. Along the paper, the four dimensional Galilean space will be denoted by \( \mathbb{G}_4 \).

Given two vectors \( a = (a_1, a_2, a_3, a_4) \) and \( b = (b_1, b_2, b_3, b_4) \), then the Galilean scalar product between these vectors is, as in [20], defined by

\[
\langle a, b \rangle_{\mathbb{G}_4} = \begin{cases} 
0 & \text{if } a_1 \neq 0 \land b_1 \neq 0, \\
a_2 b_2 + a_3 b_3 + a_4 b_4 & \text{if } a_1 = 0 \land b_1 = 0.
\end{cases}
\]

For the vectors \( a = (a_1, a_2, a_3, a_4) \), \( b = (b_1, b_2, b_3, b_4) \), and \( c = (c_1, c_2, c_3, c_4) \), the cross product in the \( \mathbb{G}_4 \) is, as in [20], given by

\[
(a \wedge b \wedge c)_{\mathbb{G}_4} = \begin{vmatrix}
0 & e_2 & e_3 & e_4 \\
a_1 & a_2 & a_3 & a_4 \\
b_1 & b_2 & b_3 & b_4 \\
c_1 & c_2 & c_3 & c_4
\end{vmatrix}, \quad \text{if } a_1 \neq 0, b_1 \neq 0 \land c_1 \neq 0,
\]

\[
= \begin{vmatrix}
e_1 & e_2 & e_3 & e_4 \\
a_1 & a_2 & a_3 & a_4 \\
b_1 & b_2 & b_3 & b_4 \\
c_1 & c_2 & c_3 & c_4
\end{vmatrix}, \quad \text{if } a_1 = 0, b_1 = 0 \land c_1 = 0.
\]

In [20], the Galilean sphere of radius \( r \) and center \( m \) of the space \( \mathbb{G}_4 \) is defined by

\[
S^2(m, r) = \{ \varphi - m \in \mathbb{G}_4 | \varphi - m, \varphi - m)_{\mathbb{G}_4} = + r^2 \}.
\]

A curve \( \alpha : I \rightarrow \mathbb{G}_4 \) of the class \( C^r (r \geq 4) \) in the Galilean space \( \mathbb{G}_4 \) is defined by the parametrization:

\[
\alpha(s) = (s, y(s), z(s), w(s)),
\]

where \( s \) is arclength parameter [20]. The orthonormal frame in \( \mathbb{G}_4 \) is defined by

\[
\begin{align}
t(s) &= \alpha'(s) = (1, y'(s), z'(s), w'(s)), \\
n(s) &= \frac{\alpha''(s)}{\|\alpha''(s)\|} = \left(0, y''(s), z''(s), w''(s)\right), \\
b(s) &= \frac{1}{\gamma(s)} \left(0, \left(\frac{1}{\kappa(s)} y''(s)''\right)'\right), \\
e(s) &= \mu t \wedge n \wedge b,
\end{align}
\]

where the coefficient \( \mu \) is taken \( \pm 1 \) to make +1 the matrix \([t, n, b] \) [20].
The curvature $\kappa(s)$, the torsion (the second curvature) $\tau(s)$, and the third curvature $\sigma(s)$ are defined by

$$
\begin{align*}
\kappa(s) &= ||\alpha''(s)||_G = \sqrt{(y''(s))^2 + (z''(s))^2 + (w''(s))^2}, \\
\tau(s) &= ||n'(s)||_G, \\
\sigma(s) &= \langle b', e \rangle_G.
\end{align*}
$$

(2)

It is well known that the set $\{t, n, b, e, \kappa, \tau, \sigma\}$ is called the Frenet-Serret apparatus of the curve $\alpha$. Here, we know that the vectors $\{t, n, b, e\}$ are mutually orthogonal vectors satisfying

$$
\begin{align*}
\langle t, t \rangle_G &= \langle n, n \rangle_G = \langle b, b \rangle_G = \langle e, e \rangle_G = 1, \\
\langle t, n \rangle_G &= \langle t, b \rangle_G = \langle t, e \rangle_G = \langle n, b \rangle_G = \langle n, e \rangle_G = \langle b, e \rangle_G = 0.
\end{align*}
$$

The vectors $t, n, b,$ and $e$ in represent the tangent, the principal normal, the binormal, and the trinormal vectors of $\alpha$, respectively. The Frenet derivative formulas can be given as in [20] in $\mathbb{G}_4$

$$
\begin{align*}
t' &= \kappa(s)n(s), \\
n' &= \tau(s)b(s), \\
b' &= -\tau(s)n(s) + \sigma(s)e(s), \\
e' &= -\sigma(s)b(s).
\end{align*}
$$

Definition 2.1. [12] A curve $\alpha : I \rightarrow \mathbb{G}_4$ is said to have constant curvature ratios (that is to say, it is a ccr–curve) if the quotients $\frac{\kappa}{\tau}$ and $\frac{\tau}{\sigma}$ are constant.

Definition 2.2. [21] Let $\alpha : I \rightarrow \mathbb{G}_4$ be a unit speed curve in $\mathbb{G}_4$. The curve $\alpha$ is called helix if its tangent vector $t$ makes a constant angle with a fixed direction $U$.

Definition 2.3. [2] Let $\alpha$ and $\alpha^*$ be two curves in $\mathbb{G}_4$. The curve $\alpha^*$ is called involute of the curve $\alpha$ if the tangent vector of the curve $\alpha$ at the point $\alpha(s)$ passes through the tangent vector of the curve $\alpha^*$ at the point $\alpha^*(s)$ and $\langle t, t^* \rangle = 0$, where $\{t, n, b, e\}$ and $\{t^*, n^*, b^*, e^*\}$ are Frenet frames of $\alpha$ and $\alpha^*$, respectively. Also, the curve $\alpha$ is called the evolute of the curve $\alpha^*$.

Definition 2.4. [15] A $C^\infty$–special Frenet-Serret curve $\alpha$ in $\mathbb{G}_4$ is called a Bertrand curve if there exist a $C^\infty$–special Frenet-Serret curve $\tilde{\alpha}$, distinct from $\alpha$, and a regular $C^\infty$–map $\varphi : I \rightarrow \tilde{I}$ ($\tilde{s} = \varphi(s), \frac{d\varphi(s)}{ds} \neq 0$ for all $s \in I$) such that curves $\alpha$ and $\tilde{\alpha}$ have the same principal normal line at each pair of corresponding points $\alpha(s)$ and $\tilde{\alpha}(\tilde{s}) = \tilde{\alpha}(\varphi(s))$ under $\varphi$. Here $s$ and $\tilde{s}$ are arclength parameters of $\alpha$ and $\tilde{\alpha}$, respectively. In this case, $\tilde{\alpha}$ is called a Bertrand mate of $\alpha$ and the mate of curves $(\alpha, \tilde{\alpha})$ is said to be a Bertrand mate in $\mathbb{G}_4$.

3. Spherical indicatrices of curves in $\mathbb{G}_4$

In this section, the tangent, principal normal, binormal, and trinormal spherical indicatrices of the curve $\alpha$ in $\mathbb{G}_4$ are expressed in terms of the Frenet apparatus of the curve $\alpha$. 

3.1. Tangent spherical indicatrix of a curve in $G_4$.

**Definition 3.1.** Let $\alpha(s) = (s, y(s), z(s), w(s))$ be a curve parametrized by arc-length $s$ in $G_4$. If we translate the tangent vector field of Frenet frame to the center $O$ of the unit sphere $S^3$, we obtain a spherical indicatrix which is called tangent spherical indicatrix $\alpha_t$ the curve $\alpha = \alpha(s)$.

Let $\varphi = \varphi(s_\varphi)$ be $\alpha_t$ Galilean spherical indicatrix of a regular curve $\alpha = \alpha(s)$ in $G_4$. First, we differentiate it, we have

$$\varphi' = \frac{ds_\varphi}{ds} \frac{ds_\varphi}{ds} = (0, y''(s), z''(s), w''(s)), \quad (3)$$

where we denote differentiation according to $s$ by a dash, and differentiation according to $s_\varphi$ by a dot. Taking the norm of both sides of (3), we have

$$\frac{ds_\varphi}{ds} = \kappa(s) \quad \text{and} \quad t_\varphi = n(s) = \frac{1}{\kappa(s)}(0, y''(s), z''(s), w''(s)). \quad (4)$$

Differentiating (4), then we get

$$\frac{dt_\varphi}{ds} \frac{ds_\varphi}{ds} = (0, (\frac{1}{\kappa(s)}y'')(s)', (\frac{1}{\kappa(s)}z'')(s)', (\frac{1}{\kappa(s)}w'')(s)'),$$

and $\dot{t}_\varphi = \frac{\tau(s)b(s)}{\kappa(s)}$.

Thus we have the first curvature and the principal normal vector of $\varphi$ as

$$\kappa_\varphi(s) = \|\dot{t}_\varphi\| = \frac{\tau(s)}{\kappa(s)}, \quad (5)$$

and $n_\varphi = b(s)$. Differentiating (5) with respect to $s$, we have

$$n'_\varphi = \frac{dn_\varphi}{ds_\varphi} \frac{ds_\varphi}{ds} = -\tau n + \sigma e,$$

$$n'_\varphi = \tau_\varphi b_\varphi = -\tau n + \frac{\sigma e}{\kappa}.$$ 

Hence, we find the second curvature of binormal vector of $\varphi$ as follow:

$$\tau_\varphi = \sqrt{(\frac{\tau}{\kappa})^2 + (\frac{\sigma}{\kappa})^2}, \quad (6)$$

and

$$b_\varphi = \frac{1}{\tau_\varphi}(-\tau n + \frac{\sigma}{\kappa})e.$$

The cross (exterior) product of $\mu_{\varphi} \wedge n_\varphi \wedge b_\varphi$ gives the trinormal vector field of the tangent spherical indicatrix $\alpha_t$ of $\alpha = \alpha(s)$ in $G_4$. Since $e_\varphi = \mu_{\varphi} \wedge n_\varphi \wedge b_\varphi$, we have

$$e_\varphi = \mu \frac{\kappa}{\sqrt{\tau^2 + \sigma^2}} t.$$
Since $\sigma = -e^{\prime}_b$, we find
\[ \sigma = \frac{\kappa^2 \tau}{\tau^2 + \sigma^2}. \]  
(7)

3.2. The principal normal spherical indicatrix of a curve in $G_4$.

Definition 3.2. Let $\alpha = (s, y(s), z(s), w(s))$ be a curve parametrized by arc-length $s$ in $G_4$. If we translate the principal normal vector field of Frenet frame to the center $O$ of the unit sphere $S^3_{G_4}$, we obtain a spherical indicatrix $\beta = \beta(s)$ which is called the principal normal spherical indicatrix $\alpha_n$ of a regular curve $\alpha = \alpha(s)$.

Let $\beta = \beta(s)$ be the principal normal spherical indicatrix $\alpha_n$ of a regular curve $\alpha = \alpha(s)$. We can write that
\[ \beta = \frac{d\beta}{ds} \frac{ds}{\beta} = \tau(s)b(s), \]
similar to the tangent spherical indicatrix $\alpha_t$, one can have
\[ t_{\beta} = b(s), \]  
(8)
and
\[ \frac{ds}{\beta} = \tau(s). \]  
(9)
Differentiating of the formula (8), we obtain
\[ t'_{\beta} = i_{\beta} \frac{ds}{ds} = -\tau(s)n(s) + \sigma(s)c(s), \]  
or
\[ t'_{\beta} = -n(s) + \frac{\sigma(s)}{\tau(s)}c(s). \]  
Therefore, we have the first curvature and the principal normal vector of $\beta$
\[ \kappa_{\beta}(s) = \|t'_{\beta}\| = \sqrt{1 + \left(\frac{\sigma}{\tau}\right)^2}, \]  
(10)
and
\[ n_{\beta} = \frac{1}{\kappa_{\beta}}[-n + \frac{\sigma}{\tau}]. \]  
(11)
Differentiating (11) gives
\[ n'_{\beta} = \frac{dn_{\beta}}{ds} \frac{ds}{\beta} = n_{\beta} \frac{ds}{\beta}, \text{ or } n'_{\beta} = \frac{ds}{\beta} (\tau_{\beta}b_{\beta}) = \left(\frac{1}{\kappa_{\beta}}[-n + \frac{\sigma}{\tau}c]\right)'. \]  
Thus, the torsion and the binormal vector of $\beta$ are expressed as
\[ \tau_{\beta} = \left(\frac{1}{\kappa_{\beta}}(1 + \left(\frac{\sigma}{\tau}\right)^2)\right)' \]  
(12)
and
\[ b_{\beta} = -\left(\frac{1}{\kappa_{\beta}}y'n - b + \left(\frac{\sigma}{\tau}\right)'\right)\left(\frac{1}{\kappa_{\beta}}\right)' + \frac{1}{\kappa_{\beta}}c. \]
Calculating \( \mu(t_\beta \wedge n_\beta \wedge b_\beta) \), we get

\[
e_\beta = \mu\left( \frac{1}{\kappa_\beta} \right)' t_
\]

and also using the third curvature formula, we find

\[
\sigma_\beta = \left( \frac{1}{\kappa_\beta} \right)' \kappa.
\] (13)

### 3.3. The Binormal Spherical Indicatrix of a Curve in \( G_4 \)

**Definition 3.3.** Let \( \alpha(s) = (s, y(s), z(s), w(s)) \) be a curve parametrized by arclength \( s \) in \( G_4 \). If we translate the binormal vector field of Frenet frame to the center \( O \) of the unit sphere \( S^3_G \), we obtain a spherical indicatrix \( \phi = \phi(s_\phi) \) which is called the binormal spherical indicatrix \( \alpha_\phi \) of the curve \( \alpha = \alpha(s) \).

Let \( \phi = \phi(s_\phi) \) be the binormal spherical indicatrix \( \alpha_\phi \) of a regular curve \( \alpha = \alpha(s) \). In terms of the Frenet frame vector fields in \( G_4 \), one can differentiate of \( \phi \) respect to \( s \)

\[
\phi' = \frac{d\phi}{ds_\phi} \frac{ds_\phi}{ds} = -\tau(s)n(s) + \sigma(s)e(s).
\]

In terms of the Frenet frame vector fields in \( G_4 \), we have the binormal vector of the spherical indicatrix as follows:

\[
t_\phi = -\tau n + \sigma e \frac{1}{\sqrt{\tau^2 + \sigma^2}},
\] (14)

where

\[
\frac{ds_\phi}{ds} = \sqrt{\tau^2 + \sigma^2}.
\]

In order to determine the first curvature of \( \phi \), we write

\[
\kappa_\phi = \| \dot{t}_\phi \| = \frac{1}{\tau^2 + \sigma^2} \left[ \left( \frac{\tau}{\sqrt{\tau^2 + \sigma^2}} \right)' n + \left( \sqrt{\tau^2 + \sigma^2} \right)' b + \left( \frac{\sigma}{\sqrt{\tau^2 + \sigma^2}} \right)' e \right],
\] (15)

hence we arrive at

\[
\kappa_\phi = \frac{1}{\tau^2 + \sigma^2} \sqrt{((\frac{\tau}{\sqrt{\tau^2 + \sigma^2}})' n + \sqrt{\tau^2 + \sigma^2} b + \left( \frac{\sigma}{\sqrt{\tau^2 + \sigma^2}} \right)' e)^2 + \tau^2 + \sigma^2 + \left( \frac{\sigma}{\sqrt{\tau^2 + \sigma^2}} \right)^2},
\] (16)

and the normal vector field of the spherical indicatrix \( \alpha_\phi \) is obtained as follows:

\[
n_\phi = \frac{1}{\kappa_\phi (\tau^2 + \sigma^2)} \left[ -\left( \frac{\tau}{\sqrt{\tau^2 + \sigma^2}} \right)' n + \sqrt{\tau^2 + \sigma^2} b + \left( \frac{\sigma}{\sqrt{\tau^2 + \sigma^2}} \right)' e \right].
\] (17)

Differentiating (17) gives

\[
n'_\phi = \frac{dn_\phi}{ds_\phi} \frac{ds_\phi}{ds} = \tau_\phi b_\phi \frac{ds_\phi}{ds}.
\]
or
\[
\tau_\phi b_\phi = \frac{1}{\sqrt{\tau^2 + \sigma^2}} \left( -\frac{1}{\kappa_\phi(\tau^2 + \sigma^2)} \left( \frac{1}{\sqrt{\tau^2 + \sigma^2}} \right)' \right)'' + \tau \sqrt{\tau^2 + \sigma^2} \\
- \left( \frac{1}{\kappa_\phi(\tau^2 + \sigma^2)} \right) \frac{\tau}{\sqrt{\tau^2 + \sigma^2}} \left( \frac{1}{\sqrt{\tau^2 + \sigma^2}} \right)' n + \frac{1}{\kappa_\phi(\tau^2 + \sigma^2)} \left( \sqrt{\tau^2 + \sigma^2} \right)' \tau \\
- \left( \frac{1}{\kappa_\phi(\tau^2 + \sigma^2)} \right) \frac{\tau}{\sqrt{\tau^2 + \sigma^2}} \left( \frac{1}{\sqrt{\tau^2 + \sigma^2}} \right)' \sigma \\
+ \left( \frac{1}{\kappa_\phi(\tau^2 + \sigma^2)} \right) \frac{\tau}{\sqrt{\tau^2 + \sigma^2}} \left( \frac{1}{\sqrt{\tau^2 + \sigma^2}} \right)' e.
\]

For (18), using the expression \( \tau_\phi b_\phi = \eta(s) \), then we obtain
\[
\tau_\phi = \|\eta(s)\|
\]
and also
\[
b_\phi = \frac{\eta(s)}{\|\eta(s)\|},
\]
where \( \eta_i \) are the components of the \( \eta(s) \) (\( i = 1, 2, 3, 4 \)),
\[
\eta_i(s) = \eta_1(s) + \eta_2(s) + \eta_3(s) + \eta_4(s).
\]

By the cross product \( \mu b \wedge n b \wedge b_\phi \) we find
\[
e_\phi = \frac{1}{\kappa^2(\tau^2 + \sigma^2)} \left\{ \tau \left( \frac{\sigma}{\sqrt{\tau^2 + \sigma^2}} \right)' \eta_1 - \eta_4 \sqrt{\tau^2 + \sigma^2} \\
- \sigma \left[ \eta_1 \left( \frac{\tau}{\sqrt{\tau^2 + \sigma^2}} \right)' + \eta_2 \sqrt{\tau^2 + \sigma^2} \right] \right\},
\]
we express derivative of \( e_\phi \) so that
\[
e_\phi' = \xi(s).
\]

Using the third curvature formula, we have
\[
\sigma_\phi = -e_\phi' b_\phi,
\]
and substituting (19) and (20) into (21), we obtain
\[
\sigma_\phi = -\frac{\xi(s) \eta(s)}{\|\eta(s)\|}.
\]

3.4. **The trinormal spherical indicatrix of a curve in \( G_4 \).**

**Definition 3.4.** Let \( \alpha(s) = (s, y(s), z(s), w(s)) \) be a curve parametrized by arc-length \( s \) in \( G_4 \). If we translate the trinormal vector field of Frenet frame to the center \( O \) of the unit sphere \( S^3_1 \), we obtain a spherical indicatrix \( \psi = \psi(s_\psi) \) which is called the trinormal spherical indicatrix \( \alpha_\psi \) of the curve \( \alpha = \alpha(s) \).

Let \( \psi = \psi(s_\psi) \) be the trinormal spherical indicatrix \( \alpha_\psi \) of the curve \( \alpha = \alpha(s) \). Differentiating \( \psi = \psi(s_\psi) \) respect to \( s \) gives
\[
\psi' = \frac{d\psi}{ds_\psi} \frac{ds_\psi}{ds} = -\sigma(s)b(s).
\]
The tangent vector of the trinormal spherical indicatrix is obtained as
\[ t_\psi = -b, \] (22)
and \[ \|\psi\| = \frac{ds_\psi}{ds} = \sigma. \]

Differentiating (22) we obtain
\[ \dot{t}_\psi = \kappa_\psi n_\sigma = \tau n - \sigma e, \]
then one can easily have the principal normal vector and the first curvature
\[ n_\psi = \tau n - \frac{\sigma}{\sqrt{\tau^2 + \sigma^2}} e, \] (23)
and
\[ \kappa_\psi = \sqrt{1 + (\frac{\tau}{\sigma})^2}, \] (24)
respectively. Differentiating (23) we get
\[ n'_\psi = \frac{dn_\psi}{ds_\psi} \frac{ds_\psi}{ds} = [(\frac{1}{\sqrt{\tau^2 + \sigma^2}})'\tau + \frac{\tau'}{\sqrt{\tau^2 + \sigma^2}}]n + \sqrt{\tau^2 + \sigma^2}b \\
-[(\frac{1}{\sqrt{\tau^2 + \sigma^2}})'\sigma + \frac{\sigma'}{\sqrt{\tau^2 + \sigma^2}}]e. \] (25)

Taking the norm of both sides of (25), we obtain the second curvature as follows:
\[ \tau_\psi = \frac{1}{\sigma} \sqrt{\tau^2(\frac{1}{\sqrt{\tau^2 + \sigma^2}})'^2 + \frac{\tau'}{\sqrt{\tau^2 + \sigma^2}}^2 + \tau^2 + \sigma^2 + \frac{\tau^2}{\tau^2 + \sigma^2} + (\frac{1}{\sqrt{\tau^2 + \sigma^2}})^2\sigma^2 + \frac{\sigma'^2}{\tau^2 + \sigma^2}} = \Gamma(s). \] (26)

To determine the binormal vector field, we express
\[ b_\psi = \frac{1}{\Gamma(s)} \left\{ \left[(\frac{1}{\sqrt{\tau^2 + \sigma^2}})'\tau + \frac{\tau'}{\sqrt{\tau^2 + \sigma^2}}\right]n \\
+ \sqrt{\tau^2 + \sigma^2}b - \left[(\frac{1}{\sqrt{\tau^2 + \sigma^2}})'\sigma + \frac{\sigma'}{\sqrt{\tau^2 + \sigma^2}}\right]e \right\}. \]

Finally, let us form the vector \( \mu t_\psi \land n_\psi \land b_\psi \) as
\[ e_\psi = \mu[\sigma(\frac{\tau}{\sqrt{\tau^2 + \sigma^2}})' - \tau(\frac{\sigma}{\sqrt{\tau^2 + \sigma^2}})]t. \]

4. CHARACTERIZATIONS OF THE SPHERICAL INDICATRICES OF CURVES IN \( G_4 \)

**Theorem 4.1.** Let \( \alpha = \alpha(s) \) be a unit speed curve and \( \varphi(s_\varphi) \) be its tangent spherical indicatrix. If \( \alpha \) is a ccr–curve or a helix (i.e. \( W \) curve), then \( \varphi \) is also a helix in \( G_4 \).
Proof. Let \( \alpha = \alpha(s) \) be a unit speed ccr–curve in \( \mathbb{G}_4 \). Then, we know that
\[
 l_1 = \frac{T}{\kappa} = \text{const.} \quad \text{and} \quad l_2 = \frac{\sigma}{\kappa} = \text{const.}
\] (27)
From (5), (6), and (7), we have
\[
 \kappa \phi = l_1, \quad \tau \phi = \sqrt{l_1^2(1 + l_2^2)}, \quad \sigma \phi = \frac{1}{l_1^2(1 + l_2^2)},
\] respectively. Therefore \( \varphi(s) \) is also helix. The condition for \( \alpha \) to be helix can be immediately seen by (27).

By this theorem , it is presented that a characterization of the tangent spherical indicatrix is associated to the Frenet-Serret curvature ratios to be constant (or helices). It is also observed that the mentioned indicatrix can be a helix, so one can ask whether this tangent spherical indicatrix is a general helix or not? Therefore it is characterized by the following statements.

**Theorem 4.2.** Let \( \alpha = \alpha(s) \) be a unit speed ccr–curve and \( \varphi = \varphi(s) \) be its tangent spherical indicatrix. If \( \varphi \) is a general helix, then there exists a relation among the Frenet-Serret curvatures of \( \alpha \) as
\[
 \varphi = c_1 t + c_2 n + c_3 b - c_3 \int_0^s \sigma dsc_\varphi.
\]
Proof. Let \( \alpha = \alpha(s) \) be a unit speed curve and \( \varphi = \varphi(s) \) be its tangent spherical indicatrix in \( \mathbb{G}_4 \). If \( \varphi = \varphi(s) \) is a general helix, then for a constant vector \( U \), we can express
\[
 \langle t, U \rangle = \text{const.},
\] (29)
Differentiating (29), we obtain \( \kappa \langle n, U \rangle = 0 \). For \( \kappa \neq 0 \), we have
\[
 \langle n, U \rangle = \text{const.}
\] (30)
One can write linear combination of \( \{ t, n, b, e \} \) of the constant vector \( U \) as
\[
 U = \varepsilon_1 t + \varepsilon_2 n + \varepsilon_3 b + \varepsilon_4 e.
\] (31)
Differentiating (31) respect to \( s \), we have the following system of ordinary differential equations
\[
 \begin{cases}
 \varepsilon'_1 = 0, \\
 \varepsilon_1 \kappa + \varepsilon'_2 - \varepsilon_3 \tau = 0, \\
 \varepsilon'_3 + \varepsilon_2 \tau - \varepsilon_4 \sigma = 0, \\
 \varepsilon_3 \sigma + \varepsilon'_4 = 0.
 \end{cases}
\] (32)
We know that \( \varepsilon_2 = c_2 \neq 0 \) is a constant. Moreover, from (32), we get \( \varepsilon_1 = c_1 \) constant. Using this system, we have two differential equations due to \( \varepsilon_3 \) as
\[
 \begin{cases}
 \varepsilon'_3 \left( \frac{T}{\kappa} \right) + \varepsilon_3 \left( \frac{T}{\kappa} \right)' = 0, \\
 \left( \frac{\varepsilon'_3}{\sigma} \right)' + \varepsilon_3 \left( \frac{T}{\kappa} \right)' + \varepsilon_3 \sigma = 0.
 \end{cases}
\] (33)
Suppose $\alpha = \alpha(s)$ is a unit speed $ccr$–curve and $\varphi = \varphi(s, \varphi)$ is its tangent spherical indicatrix, then the relations (33) are satisfied. We know that $ccr$–curve has constant curvature ratios such that $\frac{\kappa}{\tau} = l_1 = \text{const.}$, and $\frac{\tau}{\sigma} = \text{const}$. Therefore the differential equations (33) turn into the following form:

$$
\begin{cases}
\frac{1}{l_1} \frac{\varepsilon_3'}{3} = 0, \\
(\frac{\varepsilon_3'}{\sigma})' + \varepsilon_3 \sigma = 0,
\end{cases}
$$

from (34), we get $\varepsilon_3 = c_3 = \text{const.}$ \hfill $\square$

**Corollary 4.3.** The fixed direction (constant vector $U$) can be composed by the components

$$
\begin{cases}
\varepsilon_1 = c_1 = \text{const.}, \\
\varepsilon_2 = c_2 = \text{const.}, \\
\varepsilon_3 = c_3 = \text{const.}, \\
\varepsilon_4 = -c_3 \int_0^s \sigma ds.
\end{cases}
$$

**Theorem 4.4.** Given that $X = X(s), Y = Y(s)$ are curves in $G_4$, and let the curvature $\sqrt{(\tau_X)^2 + (\sigma_X)^2}$ of $X = X(s)$ be constant. If trinormal of $X = X(s)$ is tangent indicatrix of $Y = Y(s)$, then $\sigma_X$ is constant.

**Proof.** Let’s calculate Frenet apparatus of $Y = Y(s)$. Consider the Frenet apparatus of curve $X = X(s)$, and $Y = Y(s)$, respectively, $\{t_X, n_X, b_X, e_X, \kappa_X, \tau_X, \sigma_X\}$ and $\{t_Y, n_Y, b_Y, e_Y, \kappa_Y, \tau_Y, \sigma_Y\}$. Suppose that $s_Y$ is the parameterized arc-length of $Y = Y(s)$. Then, we can write

$$
Y = \int_0^s e_X(s) ds.
$$

Differentiating both sides of (35) respect to $s$, we get

$$
\frac{dY}{ds} = \frac{dY}{ds_Y} \frac{ds_Y}{ds} = e_X.
$$

Since

$$
\frac{dY}{ds_Y} = t_Y,
$$

from (36), we find

$$
t_Y \frac{ds_Y}{ds} = e_X.
$$

Using (37) and (38) in (36), we obtain

$$
t_Y = e_X,
$$

and

$$
\frac{ds_Y}{ds} = 1.
$$

Taking the derivative of (39) respect to $s$, we have

$$
\kappa_Y n_Y = -\sigma_X b_X.
$$
From (40), we get
\[ n_Y = -b_X, \]
and \( \kappa_Y = \sigma_X \). Differentiating (41) gives
\[ \tau_Y b_Y = \tau_X n_X - \sigma_X e_X, \]
and using the expression \( \tau_Y = \sqrt{\tau_X^2 + \sigma_X^2} \), we obtain
\[ b_Y = \frac{\tau_X n_X - \sigma_X e_X}{\sqrt{\tau_X^2 + \sigma_X^2}}. \]
(42)

If exterior product \( t_Y \wedge n_Y \wedge b_Y \) is calculated, we get
\[ e_Y = \frac{t_X}{\sqrt{\tau_X^2 + \sigma_X^2}}, \]
(43)
and differentiating (43) respect to \( s \), we find
\[ -\sigma_Y b_Y = \frac{\kappa_X n_X}{\sqrt{\tau_X^2 + \sigma_X^2}} + \left( \frac{1}{\sqrt{\tau_X^2 + \sigma_X^2}} \right)' t_X. \]
Since \( r = \sqrt{\tau_X^2 + \sigma_X^2} \) is constant, then
\[ \sigma_Y = \sigma \frac{\kappa_X}{r}, \quad \text{and} \quad b_Y = -n_X. \]

Therefore, we arrive at
\[ \sigma_Y = \frac{\kappa_X}{\sqrt{\tau_X^2 + \sigma_X^2}}, \quad \text{and} \quad \sigma_X = \frac{1}{\sqrt{\left( \frac{\tau}{\kappa_X} \right)^2 + \left( \frac{\sigma_X}{\kappa_X} \right)^2}}. \]

So, the third curvature of \( X = X(s) \) is as follows:
\[ \sigma_X = \frac{1}{\sqrt{l_1^2 + l_1 l_2}}. \]

Since \( l_1 \) and \( l_2 \) are constant, then \( \sigma_X = \text{const.} \)

\[ \square \]

**Theorem 4.5.** Let \( \alpha(s) = (s, y(s), z(s), w(s)) \) be a unit speed curve and \( \beta = \beta(s_\beta) \) be its principal normal spherical indicatrix. If \( \alpha \) is a ccr−curve helix (i.e. W-curve), then \( \beta \) is also a plane curve.

**Proof.** Let \( \alpha = \alpha(s) \) be unit speed ccr−curve. We know that
\[ \frac{\kappa}{\tau} = \frac{1}{l_1} = \text{const.} \quad \text{and} \quad \frac{\tau}{\sigma} = \frac{1}{l_2} = \text{const.} \]
From (10) and (12), we get the first and second curvatures of \( \beta = \beta(s_\beta) \) as follows
\[ \kappa_\beta = \sqrt{1 + l_1^2} = \text{const.}, \quad \text{and} \quad \tau_\beta = 0 = \text{const.} \]
Substituting \( \kappa_\beta \) and \( \tau_\beta \) to the first part of formula a spherical curve has to satisfy, it is seen that \( \beta(s_\beta) \) is a spherical curve. By the way, we get
\[ \sigma_\beta = \left( \frac{1}{\sqrt{1 + l_1^2}} \right)^2 \kappa = 0 = \text{const.} \]
Therefore $\beta(s)$ is also a flat curve. □

**Theorem 4.6.** Let $\psi$ and $\delta$ be unit speed curves such that $\psi$ is trinormal spherical indicatrix of $\delta$, and $\delta$ be an evolute of $\psi$. The Frenet apparatus of $\psi \{t_\psi, n_\psi, b_\psi, e_\psi, \kappa_\psi, \tau_\psi, \sigma_\psi\}$ can be formed according to the Frenet apparatus of $\delta \{t_\delta, n_\delta, b_\delta, e_\delta, \kappa_\delta, \tau_\delta, \sigma_\delta\}$.

**Proof.** From definition of involute-evolute curve pair we write

$$\delta = \psi + \lambda t_\psi, \quad (44)$$

and differentiating (44) respect to $s$ we obtain

$$\frac{d\delta}{ds} \frac{ds}{ds} = t + \frac{d\lambda}{ds} t_\psi + \lambda t'_\psi. \quad (45)$$

Recalling definition of involute and evolute we can say

$$t_\psi \perp t_\delta,$$

hence we have

$$1 + \frac{d\lambda}{ds} = 0,$$

and we find

$$\lambda = c - s,$$

where $c$ is constant. Rewriting (44), we have

$$\delta = \psi + (c - s)t_\psi, \quad (46)$$

and differentiating (46) respect to $s$, we have

$$t_\delta \frac{ds}{ds} = -(c - s)b, \quad (47)$$

and

$$t_\delta = -b.$$

Taking the norm of both sides of (46) we have

$$\frac{ds}{ds} = (c - s),$$

and

$$\dot{n}_\delta = \kappa_\delta n_\delta = -\tau n + \sigma e, \quad (48)$$

then one can easily have the principal vector and the first curvature

$$n_\delta = \frac{-\tau n + \sigma e}{\sqrt{\tau^2 + \sigma^2}}, \quad \kappa_\delta = \|\dot{n}_\delta\| = \sqrt{\tau^2 + \sigma^2}. \quad (49)$$

Differentiating (48) gives

$$n'_\delta = \frac{1}{c - s} \left\{ (\frac{-\tau}{\sqrt{\tau^2 + \sigma^2}}) - \tau' \right\}n + (\frac{-\tau^2 - \sigma^2}{\sqrt{\tau^2 + \sigma^2}})b$$

$$+ (\frac{-\tau^2 - \sigma^2}{\sqrt{\tau^2 + \sigma^2}}) + \sigma'e \right\}. \quad (50)$$

Let us denote the derivative of the principal normal vector field as

$$n'_\delta = P(s), \quad (51)$$
where \( P(s) = (p_1(s), p_2(s), p_3(s), p_4(s)) \). Taking the norm of both sides of (49), we have the second curvature and binormal vector as follows:
\[
\tau_\delta b_\delta = P'(s),
\]
and
\[
\tau_\delta = P'(s) \text{ and } b_\delta = \frac{P'(s)}{\tau_\delta}.
\]
Calculating \( t_\delta \wedge n_\delta \wedge b_\delta \) gives
\[
e_\delta = \frac{\tau e - \sigma n}{\tau_\delta \sqrt{\tau^2 + \sigma^2}} p_1'(s),
\]
and using the third curvature formula, we obtain
\[
\sigma_\delta = -e_\delta b_\delta,
\]
and
\[
\sigma_\delta = -\left( \frac{\tau e - \sigma n}{\tau_\delta \sqrt{\tau^2 + \sigma^2}} p_1'(s) \right)' p_1'(s) \frac{1}{\tau_\delta}.
\]

**Theorem 4.7.** Let \( \alpha = \alpha(s) \) be regular curve in \( \mathbb{G}_4 \). The curves \( \beta \) and \( \psi \) which are spherical indicatrices of \( \alpha \) are Bertrand mates. Also the curve \( \beta \) is the principal normal spherical indicatrix, and \( \psi \) the trinormal spherical indicatrix of \( \alpha \).

**Proof.** Denote the principal normal vectors of \( \phi \) and \( \psi \), \( n_\beta \) and \( n_\psi \), respectively, and the principal normal vectors are given
\[
n_\beta = -\frac{\tau n + \sigma e}{\sqrt{\tau^2 + \sigma^2}} \text{ and } n_\phi = \frac{\tau n - \sigma e}{\sqrt{\tau^2 + \sigma^2}}.
\]
It can be seen that \( n_\beta = -n_\phi \). So the principal normal vectors of spherical indicatrices \( \beta \) and \( \psi \) are linear dependent. Hence these curves are Bertrand mates. \( \square \)

**Theorem 4.8.** Let \( \alpha = \alpha(s) \) be a regular curve in \( \mathbb{G}_4 \). Let us denote the principal normal, binormal, and trinormal spherical indicatrices of \( \alpha \) by \( \beta, \phi \), and \( \psi \), respectively. Both of \( \beta \) and \( \psi \) which are spherical indicatrices of \( \alpha \) are spherical involutes for the binormal spherical indicatrices \( \phi \) of \( \alpha \).

**Proof.** Let us denote the tangent vectors of the spherical indicatrices \( \beta, \phi \), and \( \psi \) as \( t_\beta, t_\phi \), and \( t_\psi \), respectively. By (8), (14), and (22), these tangent vectors are as follows
\[
t_\beta = b, t_\phi = -\frac{\tau n + \sigma e}{\sqrt{\tau^2 + \sigma^2}}, \text{ and } t_\psi = -b.
\]
If the inner products of these vectors are calculated, then we get
\[
\langle t_\beta, t_\phi \rangle = 0 \text{ and } \langle t_\psi, t_\phi \rangle = 0.
\]
The tangent vectors of the spherical indicatrices \( \beta, \psi \) are orthogonal to tangent vector of binormal spherical indicatrix \( \phi \). So the proof is completed. \( \square \)
obtained as Frenet elements of the tangent indicatrix \langle G \rangle.

S. Yılmaz and Y. Ünlütürk

The third curvature is calculated as \( \sigma \), \( \tau \), and \( \kappa \), the tangent vector of the principal normal indicatrix is \( t \), and also the second curvature is \( \tau \), the principal normal vector of the binormal indicatrix is as \( n \), respectively. The binormal and trinormal vectors of the principal normal indicatrix are obtained as \( b \) and \( \beta \), respectively. Hence the third curvature is calculated as \( \sigma \) becomes \( 1 \), \( \phi \) respectively. The binormal and trinormal vectors of the tangent indicatrix are found as \( b \) and \( \beta \), \( \epsilon \) respectively.

Let us calculate the spherical indicatrices of the curve \( \alpha \), first let us express the Frenet elements of the tangent indicatrix \( \varphi = \varphi(s, \varphi) \) in terms of the Frenet elements of the curve \( \alpha \). Using the equations (4), (5), (6), the tangent vector of the tangent indicatrix is calculated as \( t_{\varphi} = n(s) = \frac{1}{\sqrt{2}}(0, -\cos s, -\sqrt{2}\sin s, -\cos s) \), and the first and second curvatures of the tangent indicatrix are found as \( \kappa_{\varphi} = \frac{1}{\sqrt{2}}, \tau_{\varphi} = \frac{1}{\sqrt{2}} \), respectively. The binormal and trinormal vectors of the tangent indicatrix are obtained as \( b_{\varphi} = \frac{1}{\sqrt{2}}(0, \cos s, \sqrt{2}\sin s, \cos s) \), and \( e_{\varphi} = \frac{\mu}{\sqrt{2}}(1, -\sin s, \sqrt{2}\cos s, -\sin s) \), respectively.

Let us express the Frenet elements of the principal normal indicatrix \( \beta = \beta(s, \beta) \) in terms of the Frenet elements of the curve \( \alpha \). Using the equations (8), (10), (11), and (13), the tangent vector of the principal normal indicatrix is \( t_{\beta} = n(s) = \frac{1}{\sqrt{2}}(0, \sin s, -\sqrt{2}\cos s, \sin s) \), and the first and second curvatures of the principal normal indicatrix are obtained as \( \kappa_{\beta} = 1, \tau_{\beta} = 0 \) respectively. The binormal and trinormal vectors of the principal normal indicatrix are found as \( b_{\beta} = \frac{1}{\sqrt{2}}(0, -\sin s, \sqrt{2}\cos s, -\sin s) \), and \( e_{\beta} = (0, 0, 0, 0) \), respectively. Hence the third curvature is calculated as \( \sigma_{\beta} = 0 \).

Let us express the Frenet elements of the binormal indicatrix \( \phi = \phi(s, \phi) \) in terms of the Frenet elements of the curve \( \alpha \). By the equations (9), (14), (16), (17) and (20), the tangent vector of the binormal indicatrix is \( t_{\phi} = \frac{1}{\sqrt{2}}(0, \cos s, \sqrt{2}\sin s, \cos s) \), and the first curvature of the binormal indicatrix is obtained as \( \kappa_{\phi} = 1 \). The principal normal vector of the binormal indicatrix is as \( n_{\phi} = b = \frac{1}{\sqrt{2}}(0, \sin s, -\sqrt{2}\cos s, \sin s) \), and also the second curvature is \( \tau_{\phi} = 1 \). The binormal and trinormal vectors of the binormal indicatrix are found as \( b_{\phi} = -n = \frac{1}{\sqrt{2}}(0, \cos s, \sqrt{2}\sin s, \cos s) \), and

\[
\alpha(s) = (s, \cos s, \sqrt{2}\sin s, \cos s) \tag{50}
\]
$e_\phi = \frac{1}{\sqrt{2}}(0, 0, 0, -\cos s)$, respectively. Hence the third curvature is calculated as $\sigma_\phi(s) = \frac{1}{4} \sin 2s$.

Finally, let us express the Frenet elements of the trinormal indicatrix $\psi = \psi(s_\psi)$ in terms of the Frenet elements of the curve $\alpha$. By equations (22), (23), (24), and (26), the tangent and principal normal vectors of the trinormal indicatrix are calculated $t_\psi = -b = \frac{1}{\sqrt{2}}(0, -\sin s, \sqrt{2} \cos s, -\sin s)$, and $n_\psi = n = \frac{1}{\sqrt{2}}(0, -\cos s, -\sqrt{2} \sin s, -\cos s)$, respectively. Also, the first curvature of the trinormal indicatrix is obtained as $\kappa_\psi = 1$, and the second curvature $\tau_\psi$ is undefined since $\frac{1}{\sigma} (\sigma = 0)$. The binormal and trinormal vectors of the trinormal indicatrix is found as $b_\psi = (0, 0, 0, 0)$, and $e_\psi = (0, 0, 0, 0)$, respectively. Hence the third curvature is $\sigma_\psi(s) = 0$.

6. CONCLUDING REMARKS

In this study, the tangent, principal normal, binormal, and trinormal spherical indicatrices of a regular curve were obtained in 4D Galilean space. Then their Frenet elements of these four special curves were found in terms of the Frenet elements of the original curve at the same space. Moreover, using Frenet elements of spherical indicatrix curves, some theorems were given characterizing these special curves as ccr−curves, general helix, involute-evolute curve pairs, and Bertrand mates. As an open problem, all the results in this study can be studied in pseudo-Galilean spaces.
